

# How does the internet work?

# **Start at the beginning**

If we visit `handbook.suncoast.io` how does our browser know where to go?

What are the technologies and processes involved in making this work?

# **Domains and Hosts**

<https://handbook.suncoast.io>

A man with a beard and long hair, wearing a dark suit jacket, white shirt, and tie, is sitting in a chair. He is looking towards the right. The room is dimly lit, with a typewriter on a desk to the right and a window in the background. The text "But where is it?" is overlaid in the center of the image.

**But where is it?**

# IP Address

- Once the browser realizes you wish to visit `handbook.suncoast.io` it must figure out how to address the server.
- The internet itself does not deal in terms of names like `handbook.suncoast.io` but in terms of a numerical address in the form `1.2.3.4` or `192.168.145.241`.

# DNS

So how does the browser know to find the IP Address of handbook.suncoast.io?

It uses a service known as DNS (Domain Name Services).

Every client has a preset list of IP Addresses that are equipped to perform a translation of a domain name like handbook.suncoast.io into its IP address 104.248.50.87.

The DNS process allows your computer to quickly translate the address.

- Checks defined DNS server.
- Likely your local router.
- Sees if it is recently resolved, given "Time To Live" (TTL).
- If not, check's its DNS server. Typically your ISP.

**This is a nice visualization of the DNS process.**

# Let's lookup a few addresses

*NOTE: Use nslookup if dig isn't available.*

```
dig handbook.suncoast.io
```

```
dig amazon.com
```

```
dig www.yahoo.com
```

We will see that DNS can return multiple values.

We will see examples of CNAMEs.

# **Making Connections**

## **What happens after our computer resolves the address of a server?**

- The next thing we need to do is connect to a particular *service* on that machine.
- Remember when we mentioned that part of the URL is a `protocol`. This also indicates which *service* we want to speak to.

# Port Numbers

- Each of these services will be *listening* for a connection from a client on a particular port number.
- If you think of the IP Address as a street address of an office building, you can think of the port number as which room in the building the service is in.

^ Ports 1 - 65535

^ Ports 1 - 1024 popular, require operating system privileges

# Sockets

To connect to a service on a port the computer creates something called a socket.

A socket is a virtual connection between your computer and a port on a remote computer.

Think of it like a pipe that information can flow through in both directions.

Once this socket is established we can *send* information and we can *receive* information in return.

# How do we connect to one of these ports?

Let's try connecting like the browser does.

For this, we will be using a tool named netcat.

- On Mac OS install it with: `brew install nc`
- On Windows install it with: `scoop install netcat`
- On Linux it is likely `sudo apt install netcat`

To connect: `nc handbook.suncoast.io 80`

# HTTP

Now that we are connected, how do we talk? We use the http protocol that is well documented.

# GET a page

```
GET / HTTP/1.1
```

```
Host: handbook.suncoast.io
```

(important blank line after Host:)

# Response (Headers)

- Status codes
- See this [funny list of codes](#)

<b>Range</b>	<b>Guide</b>
200–299	Everything ok
300–399	Go elsewhere
400–499	Client mistake
500–599	Server mistake

# What are other HTTP headers?

- Common headers:

<b>Header</b>	<b>Meaning</b>
Date	<i>Timestamp on Server</i>
Content-Type	<i>How should this content be interpreted</i>
Content-Length	<i>How long is this content in bytes</i>
Last-Modified	<i>When was this content last modified</i>

# Other tools

- `curl`
- `http` (`httpie`)
- `Insomnia`
